Flywheel energy storage needs to be combined with chemical energy storage

Overview

FESS can be used in conjunction with medium and long duration mechanical/thermal/chemical storages to mitigate slow ramp up times of the latter and accelerate storage response. The existing energy storage systems use various technologies, including hydro-electricity, batteries, supercapacitors, thermal storage, energy storage flywheels,[2] and others. Pumped hydro has the largest deployment so far, but it is limited by geographical locations. When energy is extracted from the system, the flywheel's rotational speed is reduced as a consequence of the principle of conservation of energy; adding energy to the. FESS is typically positioned between ultracapacitor storage (high cycle life but also very high storage cost) and battery storage, (low storage cost but limited cycle life). Similar to ultracapacitors and battery storages, FESS' response time is in the order of milliseconds and limited only by the. A flywheel energy storage system stores energy mechanically rather than chemically. It operates by converting electrical energy into rotational kinetic energy, where a heavy rotor (the flywheel) spins at high speed within a vacuum chamber.
