# **Photovoltaic panels passing the moon at night**

## Overview

---

The direct answer is two-fold: technically, yes, the moonlight contains photons that can activate a photovoltaic cell, but practically, no, it cannot generate any meaningful or useful electricity. A solar panel is fundamentally a device designed to convert incident light energy, specifically. The team has developed a method to harness the natural process of radiative cooling, allowing solar panels to convert the night sky into a power source. Here's the thing many people don't think about: moonlight isn't its own kind of light - it's just sunlight bouncing off the moon. 3% of what they would during the day. Most solar panels enter a sleep mode at night, and even if they don't, the energy produced is insignificant. But what if we told you that researchers have now found a way to generate electricity even after the sun goes down?

Thanks to a groundbreaking development in.
