# **Solar combined cycle power generation technology**

## Overview

---

The Integrated Solar Combined Cycle Power Plant (ISCC) has been introduced in the power generation sector as a technology with the potential to help reduce the costs of solar energy for electricity generation. A combined-cycle power plant is an assembly of heat engines that work in tandem from the same source of heat, converting it into mechanical energy. On land, when used to make electricity the most common type is called a combined-cycle gas turbine (CCGT) plant, which is a kind of gas-fired power. A combination of tools is used to estimate the levelized cost of electricity (LCOE) and the cost of carbon abatement (CoA) for CSP, NGCC and ISCC technologies under different natural gas prices, and at several locations experiencing different ambient temperatures and solar resources. Results show. This study investigates a combined cycle power plant (CCPP) integrated with a solar thermal field using linear parabolic collectors to simultaneously produce electricity and hydrogen. This work aims to contribute to the energy transition by exploring the best options for integrating a solar field within a combined cycle power plant.

An integrated solar combined cycle (ISCC) is a hybrid technology in which a solar thermal field is integrated within a combined-cycle plant. In ISCC plants, solar energy is used as an auxiliary heat supply, supporting the steam cycle, which results in increased generation capacity or a reduction of fossil fuel use. Thermodynamic benefits are that daily steam turbine startup losses are eliminated.
